Lecture 6

Relational Database Design by ER- and EERR-to-Relational Mapping

ER-to-Relational Mapping Algorithm
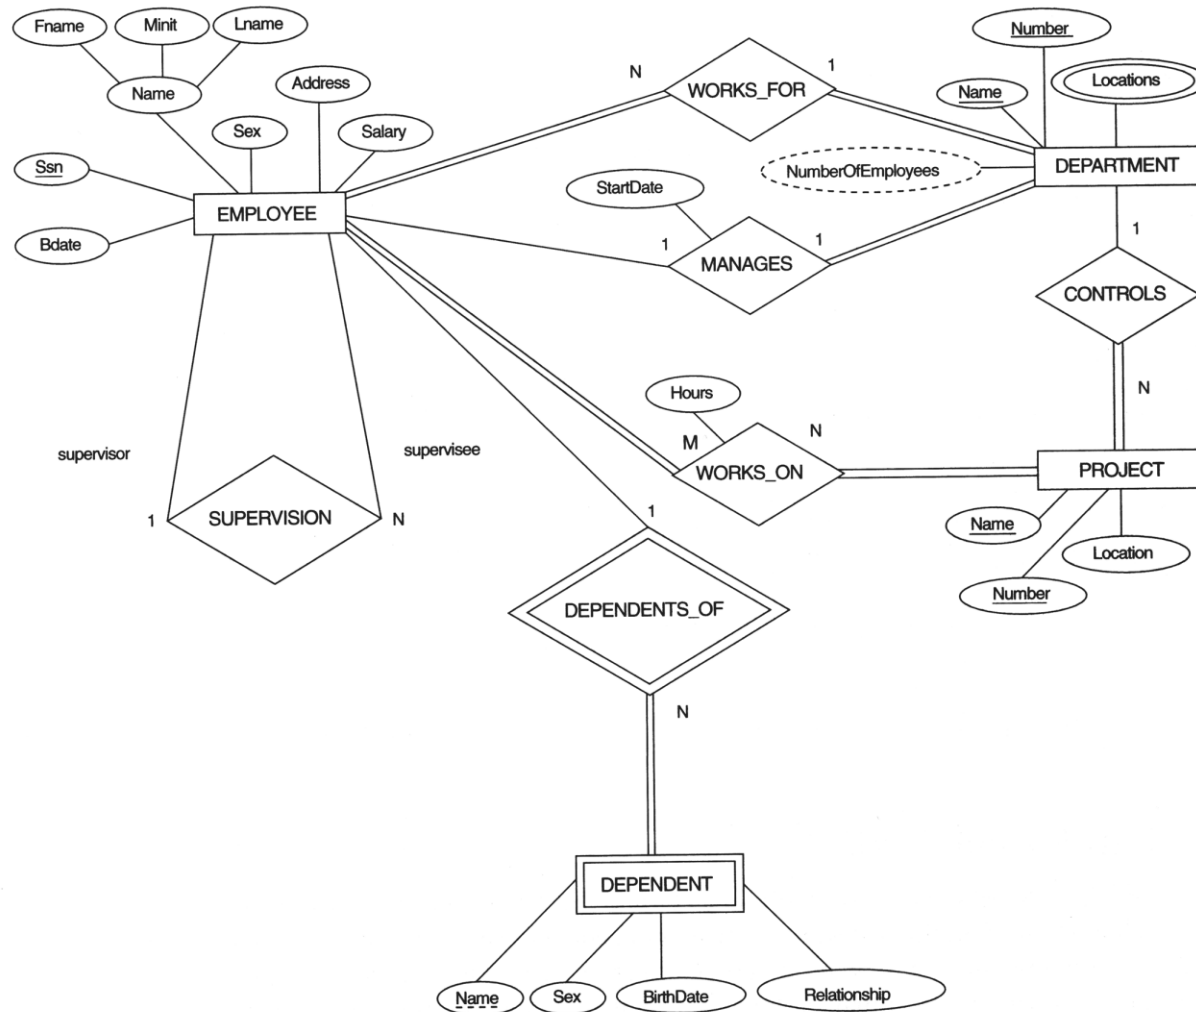

▶ Step 1: Mapping of Regular Entity Types.

- For each regular (strong) entity type E in the ER schema, create a relation R that includes all the simple attributes of E.

- Choose one of the key attributes of E as the primary key for R.

- If the chosen key of E is composite, the set of simple attributes that form it will together form the primary key of R.
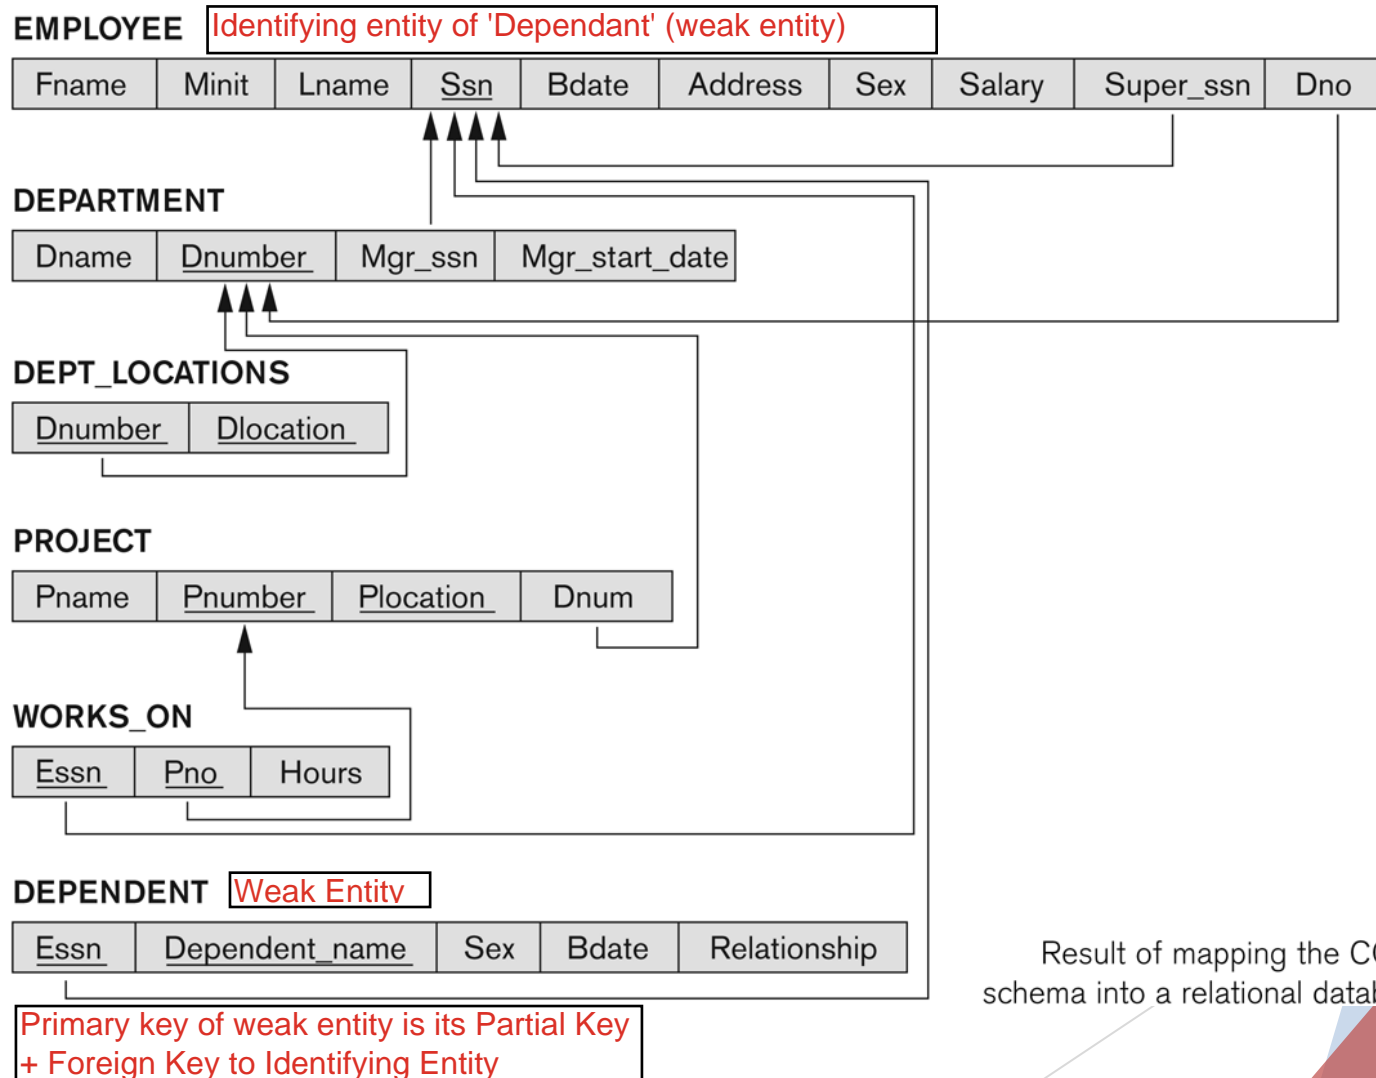

▶ Example: We create the relations EMPLOYEE, DEPARTMENT, and PROJECT in the relational schema corresponding to the regular entities in the ER diagram.

- SSN, DNUMBER, and PNUMBER are the primary keys for the relations EMPLOYEE, DEPARTMENT, and PROJECT as shown.

The ER conceptual schema diagram for the COMPANY database

Result of mapping the COMPANY ER schema into a relational schema

EMPLOYEE

Fname	Minit	Lname	Ssn	Bdate	Address	Sex	Salary	Super_ssn	Dno

Identifying entity of 'Dependant' (weak entity)

DEPARTMENT

Dname	Dnumber	Mgr_ssn	Mgr_start_date

DEPT_LOCATIONS

Dnumber	Dlocation

PROJECT

Pname	Pnumber	Plocation	Dnum

WORKS_ON

Essn	Pno	Hours

DEPENDENT   Weak Entity

Essn	Dependent_name	Sex	Bdate	Relationship

Primary key of weak entity is its Partial Key
+ Foreign Key to Identifying Entity

Result of mapping the COMPANY ER schema into a relational database schema.

ER-to-Relational Mapping Algorithm

▶ **Step 2: Mapping of Weak Entity Types**

- For each weak entity type W in the ER schema with owner entity type E, create a relation R & include all simple attributes (or simple components of composite attributes) of W as attributes of R.

- Also, include as foreign key attributes of R the primary key attribute(s) of the relation(s) that correspond to the owner entity type(s).

- The primary key of R is the *combination of* the primary key(s) of the owner(s) and the partial key of the weak entity type W, if any.

Example

- Create the relation DEPENDENT in this step to correspond to the weak entity type DEPENDENT.

  - Include the primary key SSN of the EMPLOYEE relation as a foreign key attribute of DEPENDENT (renamed to ESSN).

  - The primary key of the DEPENDENT relation is the combination {ESSN, DEPENDENT_NAME} because DEPENDENT_NAME is the partial key of DEPENDENT.

ER-to-Relational Mapping Algorithm

▶ **Step 3: Mapping of Binary 1:1 Relation Types**

- ▪ For each binary 1:1 relationship type R in the ER schema, identify the relations S and T that correspond to the entity types participating in R.

▶ There are three possible approaches:

1. **Foreign Key approach:** Choose one of the relations-say S-and include a foreign key in S the primary key of T. It is better to choose an entity type with total participation in R in the role of S.
   - ▶ Example: 1:1 relation MANAGES is mapped by choosing the participating entity type DEPARTMENT to serve in the role of S, because its participation in the MANAGES relationship type is total.

Mapping of Binary 1:1 Relation Types

2. **Merged relation option:** An alternate mapping of a 1:1 relationship type is possible by merging the two entity types and the relationship into a single relation. This may be appropriate when both participations are total.

3. **Cross-reference or relationship relation option:** The third alternative is to set up a third relation R for the purpose of cross-referencing the primary keys of the two relations S and T representing the entity types.
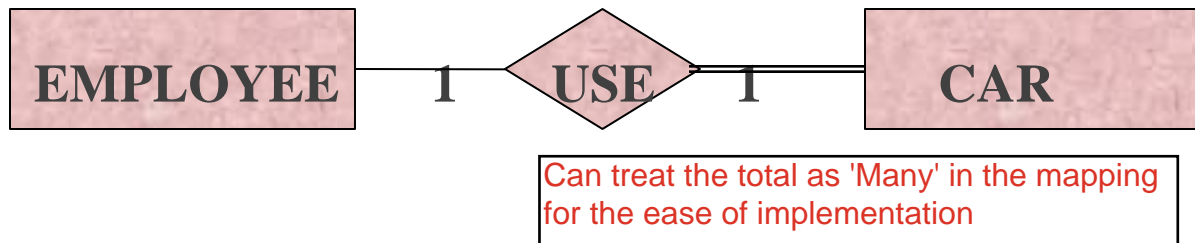

Example: A company assign a car for every employee

EMPLOYEE   USE   CAR

1   1

EMPLOYEE (EMP#,……....,CAR#,…..…..)

Other attributes of an employee   other attributes of a car

If participant is total for both entity types, put all attributes into a single table type. The identifier (key) of this table is any of the identifiers of the two entities

Suppose every company car is used by an employee, but not every employee has a company car

| EMPLOYEE | —— 1 —— ◇ USE ◇ —— 1 == | CAR |

Can treat the total as 'Many' in the mapping for the ease of implementation

EMPLOYEE (EMP#, ….…....)

CAR (CAR#,…...……, EMP#)

FK

If participant is total for only one entity type, define two table types, one for each entity. Post the identifier of the partial entity into the total entity's table type.

Suppose every employee must use a car, but not every car has to be used by an employee

| EMPLOYEE | 1 | USE | 1 | CAR |

EMPLOYEE (<u>EMP#</u>, ……..., CAR#) **FK**

CAR (<u>CAR#</u>, …..…..)

If participant is total for only one entity type, define two table types, one for each entity. Post the identifier of the partial entity into the total entity's table type.

If participant is partial for both entity types

EMPLOYEE (EMP#, ……....)

CAR (CAR#, …..)

USES (EMP#, CAR#, ….)

      FK   **FK**

**Define three table types, one for each entity and one for
the relationship that has an identifier of the
identifier of either one of the two entities' identifier**

ER-to-Relational Mapping Algorithm

- ▶ Step 4: Mapping of Binary 1:N Relationship Types.

  - ▪ For each regular binary 1:N relationship type R, identify the relation S that represent the participating entity type at the N-side of the relationship type.

  - ▪ Include as foreign key in S the primary key of the relation T that represents the other entity type participating in R.

  - ▪ Include any simple attributes of the 1:N relation type as attributes of S.

Mapping of Binary 1:N Relationship Types

Example: 1:N relationship types WORKS_FOR, CONTROLS, and SUPERVISION in the COMPANY system

- ▶ For WORKS_FOR we include the primary key DNUMBER of the DEPARTMENT relation as foreign key in the EMPLOYEE relation and call it DNO.

Mapping of Binary 1:N Relationship Types

EMPLOYEE (<u>EMP#</u>, ……..., CAR#) **FK**

CAR (<u>CAR#</u>, …..……)

Will not differ in cases of 'Total' and 'Partial' , If 'Partial' just FK may be null

Define two table types, one for each entity. Post the identifier of the "one" entity into the "many" entity's table type.

ER-to-Relational Mapping Algorithm

▶ **Step 5: Mapping of Binary M:N Relationship Types.**

- For each regular binary M:N relationship type R, *create a new relation* S to represent R.

- Include as foreign key attributes in S the primary keys of the relations that represent the participating entity types; *their combination will form the primary key* of S.

- Also include any simple attributes of the M:N relationship type (or simple components of composite attributes) as attributes of S.

Mapping of Binary M:N Relationship Types

Example: The M:N relationship type WORKS_ON from the ER diagram is mapped by creating a relation WORKS_ON in the relational database schema.

- ▶ The primary keys of the PROJECT and EMPLOYEE relations are included as foreign keys in WORKS_ON and renamed PNO and ESSN, respectively.

- ▶ Attribute HOURS in WORKS_ON represents the HOURS attribute of the relation type. The primary key of the WORKS_ON relation is the combination of the foreign key attributes {ESSN, PNO}.

Mapping of Binary M:N Relationship Types

EMPLOYEE   M   USE   N   CAR

EMPLOYEE (<u>EMP#</u>, ……...)

CAR (<u>CAR#</u>, …..…..)

USE (<u>EMP#</u> , <u>CAR#</u> , …)
      FK   FK

Same for 'Total' and 'Partial' , If both 'partial' and do not exist , there will be no tuples in the relation table.
If one of them is partial and the other is total , the relation will always have a tuple representing the relation

Define three table types, one for each entity and one for the relationship. The identifier of the relationship entity is the combination of both of the two entity's identifier.

ER-to-Relational Mapping Algorithm (contd.)

▶ **Step 6: Mapping of Multivalued attributes.**

- For each multivalued attribute A, create a new relation R. If not mapped like this, the relation schema will not be in the 1st normal form (atomicity)

- This relation R will include an attribute corresponding to A, plus the primary key attribute K-as a foreign key in R-of the relation that represents the entity type of relationship type that has A as an attribute.

- The primary key of R is the combination of A and K. If the multivalued attribute is composite, we include its simple components.

Mapping of Multivalued attributes

Example: The relation DEPT_LOCATIONS is created.

- ▶ The attribute DLOCATION represents the multivalued attribute LOCATIONS of DEPARTMENT, while DNUMBER-as foreign key-represents the primary key of the DEPARTMENT relation.

- ▶ The primary key of R is the combination of {DNUMBER, DLOCATION}.

ER-to-Relational Mapping Algorithm

▶ **Step 7: Mapping of N-ary Relationship Types.**

- For each n-ary relationship type R, where n>2, create a new relationship S to represent R.

- Include as foreign key attributes in S the primary keys of the relations that represent the participating entity types.

- Also include any simple attributes of the n-ary relationship type (or simple components of composite attributes) as attributes of S.
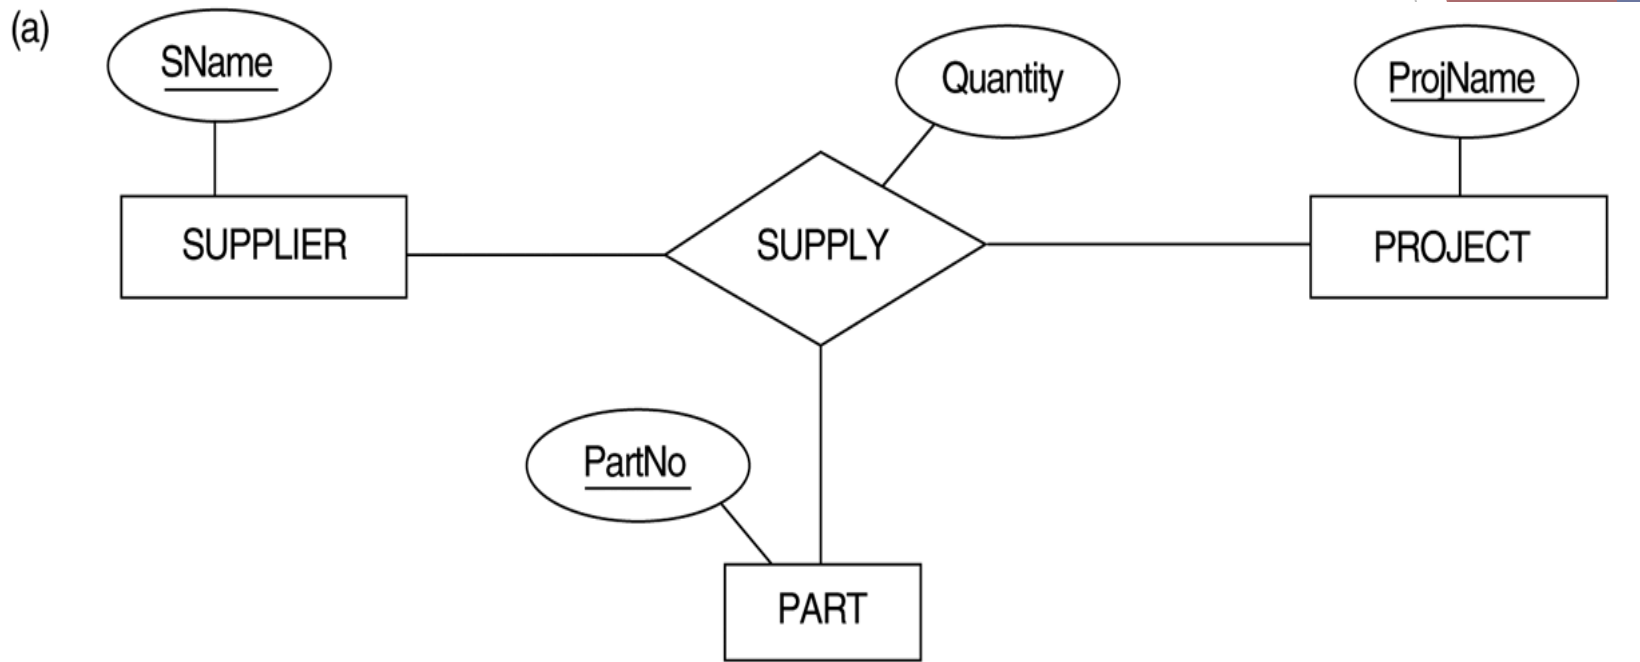

Mapping of N-ary Relationship Types

Example: The relationship type SUPPY in the ER on the next slide.

- ▶ This can be mapped to the relation SUPPLY shown in the relational schema, whose primary key is the combination of the three foreign keys {SNAME, PARTNO, PROJNAME}

Ternary relationship types
(a) The SUPPLY relationship

Mapping the *n*-ary relationship type SUPPLY

Summary of Mapping constructs and constraints

Correspondence between ER and Relational Models

ER Model	Relational Model
Entity type	"Entity" relation
1:1 or 1:N relationship type	Foreign key (or "relationship" relation)
M:N relationship type	"Relationship" relation and two foreign keys
n-ary relationship type	"Relationship" relation and n foreign keys
Simple attribute	Attribute
Composite attribute	Set of simple component attributes
Multivalued attribute	Relation and foreign key
Value set	Domain
Key attribute	Primary (or secondary) key

Necessary for 1st Normal Form

Mapping EER Model Constructs to Relations

▶ **Step8: Options for Mapping Specialization or Generalization.**

▶ Convert each specialization with m subclasses {S1, S2,....,Sm} and generalized superclass C, where the attributes of C are {k,a1,...an} and k is the (primary) key, into relational schemas using one of the four following options:

▶ Option 8A: Multiple relations-Superclass and subclasses   Each entity has its own relation (table)

▶ Option 8B: Multiple relations-Subclass relations only   Relation (table) only for subclasses

▶ Option 8C: Single relation with one type attribute   Relation only for superclass(with all attributes for subclasses)

▶ Option 8D: Single relation with multiple type attributes

Relation only for superclass(with all attributes + boolean flag for the type of subclass)

Mapping EER Model Constructs to Relations

Option 8A: Multiple relations-Superclass and subclasses

- Create a relation L for C with attributes Attrs(L) = {k,a1,...an} and PK(L) = k. Create a relation Li for each subclass Si, 1 < i < m, with the attributes

  Attrs(Li) = {k} U {attributes of Si}

and PK(Li)=k.

This option works for any specialization (total or partial, disjoint of over-lapping).

Mapping EER Model Constructs to Relations

Option 8B: Multiple relations-Subclass relations only

▶ Create a relation Li for each subclass Si,

$1 < i < m$, with the attributes

Attr(Li) = {attributes of Si} U {k,a1...,an}

and PK(Li) = k.

This option only works for a specialization whose subclasses are total (every entity in the superclass must belong to (at least) one of the subclasses).

EER diagram notation for an attribute-defined specialization on JobType.
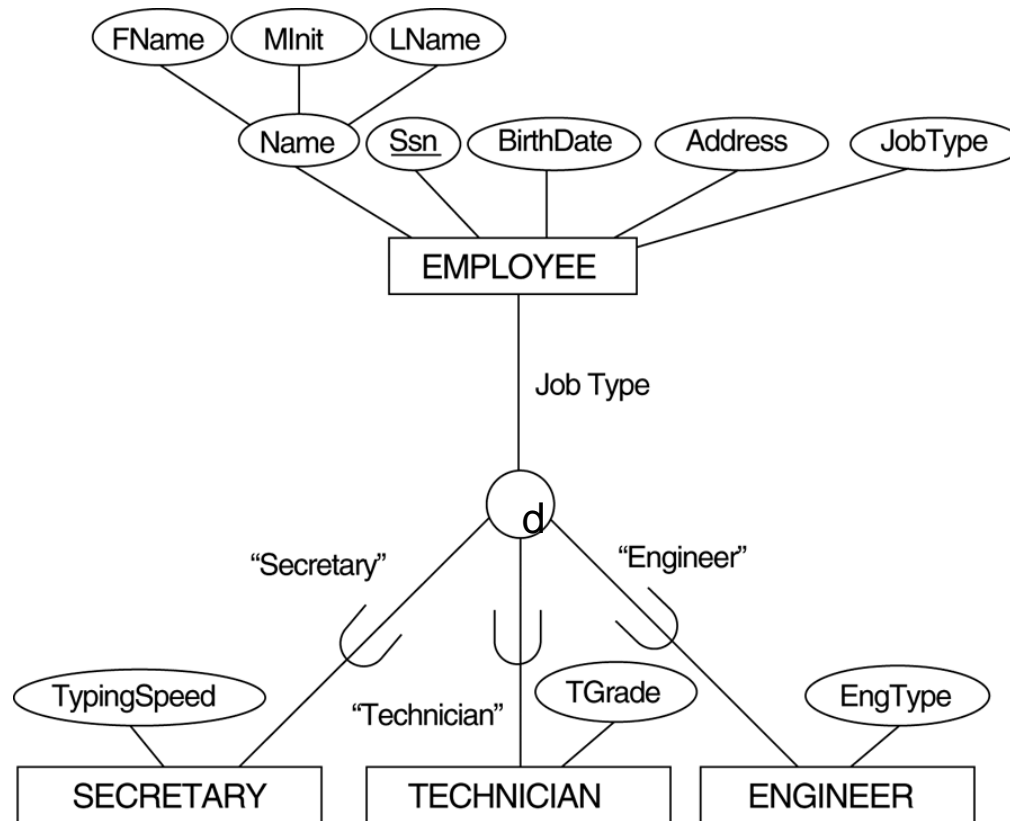

Options for mapping specialization or generalization.
(a) Mapping the EER schema using option 8A.

Generalization. (b) Generalizing CAR and TRUCK into the superclass VEHICLE.

(b)

Total (Vehicle must be one of subclasses)
+ Disjoint (must be only one of the subclasses
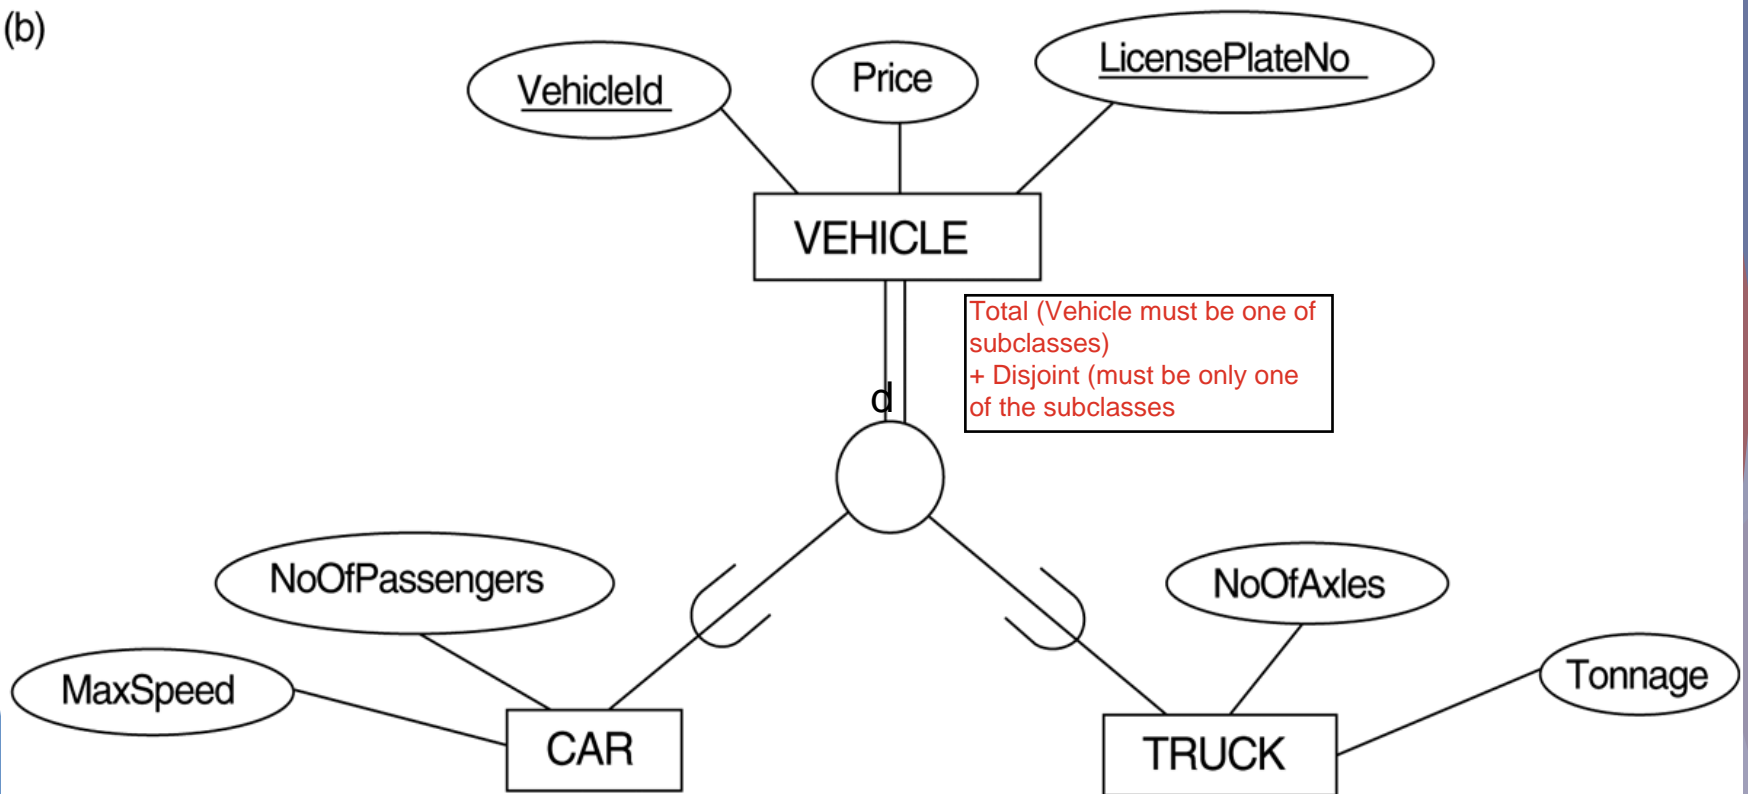

Options for mapping specialization or generalization.
(b) Mapping the EER schema using option 8B.

Only works for TOTAL, since partial means a vehicle may not be 'Car' or 'Truck' , which means that no tuple (row) can represent this

(b)

CAR

VehicleId	LicensePlateNo	Price	MaxSpeed	NoOfPassengers

TRUCK

VehicleId	LicensePlateNo	Price	NoOfAxles	

Mapping EER Model Constructs to Relations

Option 8C: Single relation with one type attribute

▶ Create a single relation L with attributes

$Attrs(L) = \{k, a_1, \ldots a_n\}$ U {attributes of S_1} U…U {attributes of S_m} U {t} and $PK(L) = k$.

The attribute t is called a type (or **discriminating**) attribute that indicates the subclass to which each tuple belongs

Mapping EER Model Constructs to Relations

Option 8D: Single relation with multiple type attributes

- ▶ Create a single relation schema L with attributes

Attrs(L) = $\{k, a_1, \ldots a_n\}$ U {attributes of S_1} U...U {attributes of S_m} U $\{t_1, t_2, \ldots, t_m\}$ and PK(L) = k. Each t_i, $1 < I < m$, is a Boolean type attribute indicating whether a tuple belongs to the subclass S_i.

EER diagram notation for an attribute-defined specialization on JobType.
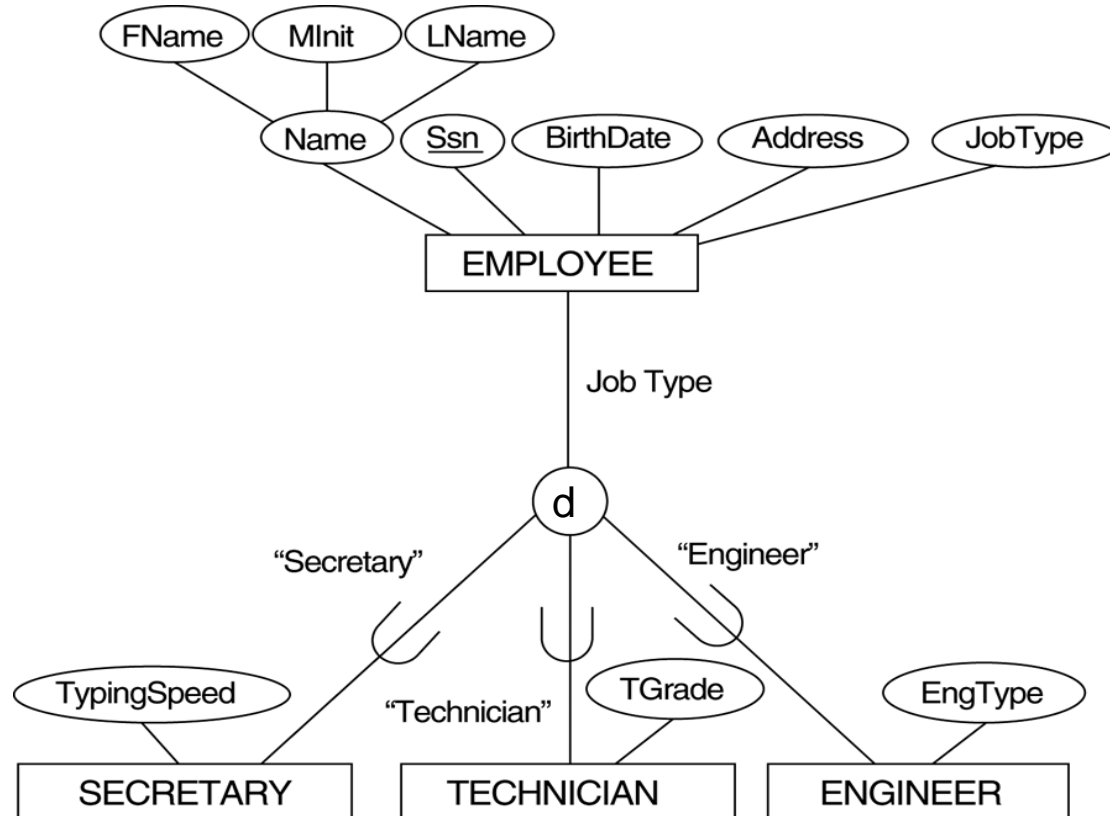

Options for mapping specialization or generalization.
(c) Mapping the EER schema using option 8C.

Not written but logically works for 'Total' and 'Parital' relations, If relation is partial and employee is not one of subclasses , all attributes of subclasses will be null, also 'JobType'. For 'Total' : JobType can be 'NOT NULL'

(c) **EMPLOYEE**

EngType

SSN	FName	MInit	LName	BirthDate	Address	JobType	TypingSpeed	TGrade	

Only one Flag is needed in case of 'Disjoint' relation since it will only be one of them

EER diagram notation for an overlapping (non-disjoint) specialization.

Where superclass can be more than one subclasses

Total (part must be a subclass).
+ Overlapping (part must be one of subclasses or both)
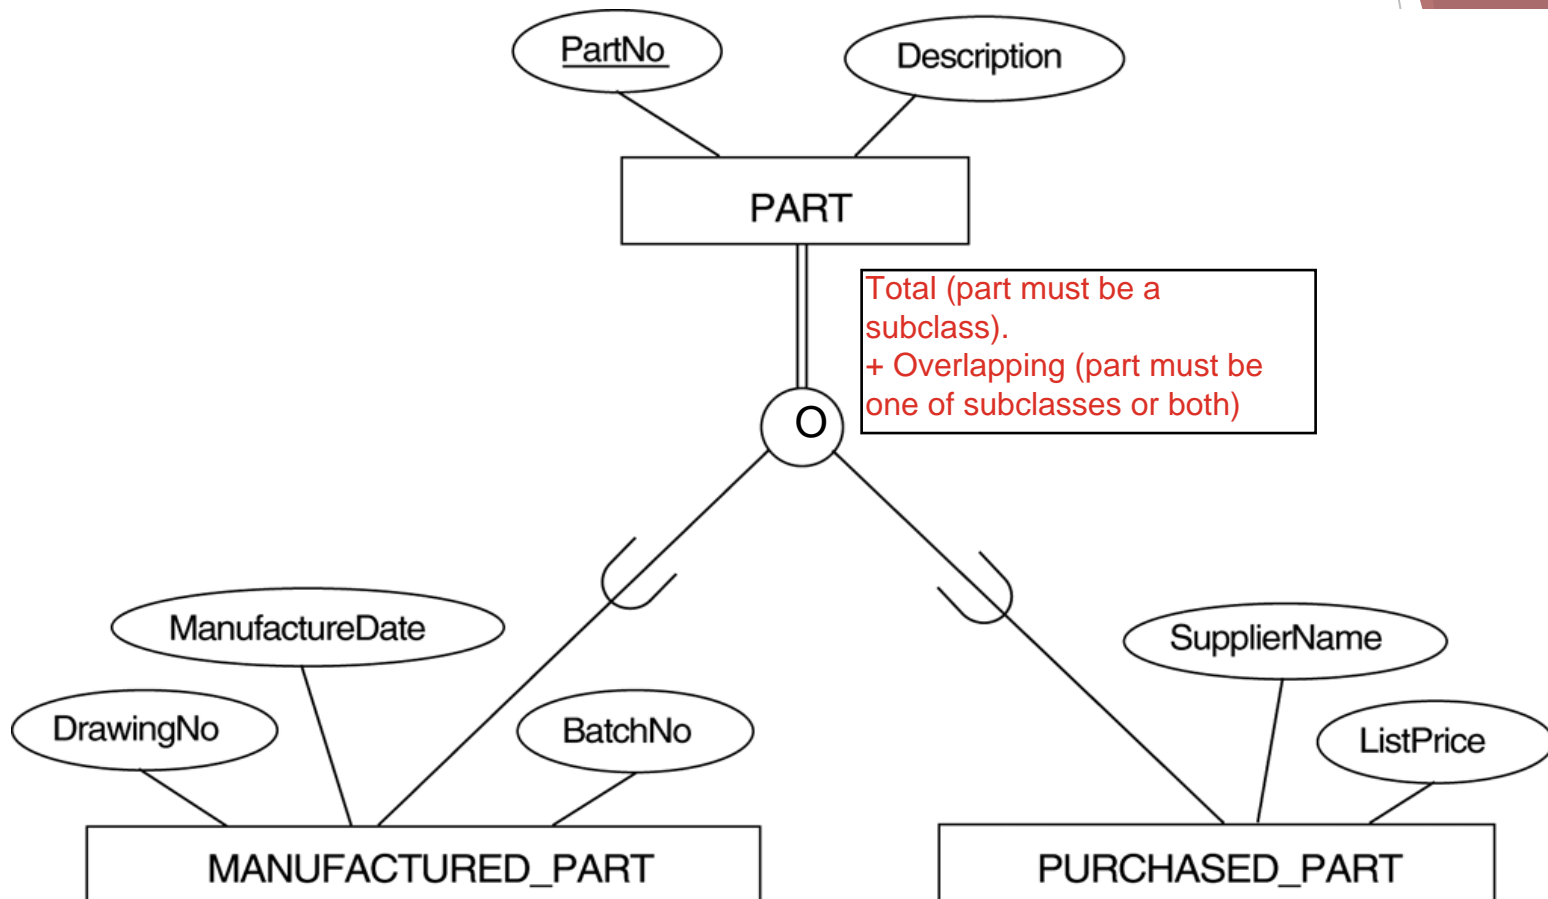

Options for mapping specialization or generalization.
(d) Mapping using option 8D with Boolean type fields Mflag and Pflag.

These boolean flags are only needed in 'Overlapping' relation, to identify existence for each type, number of boolean flags = number of subclasses

(d) PART

PartNo	Description	MFlag	DrawingNo	ManufactureDate	BatchNo	PFlag	SupplierName	ListPrice

Mapping EER Model Constructs to Relations

Mapping of Shared Subclasses (Multiple Inheritance)

- ▶ A shared subclass, such as STUDENT_ASSISTANT, is a subclass of several classes, indicating multiple inheritance. These classes must all have the same key attribute; otherwise, the shared subclass would be modeled as a category.

- ▶ We can apply any of the options discussed in Step 8 to a shared subclass, subject to the restriction discussed in Step 8 of the mapping algorithm. Below both 8C and 8D are used for the shared class STUDENT_ASSISTANT.

A specialization lattice with multiple inheritance for a UNIVERSITY database.
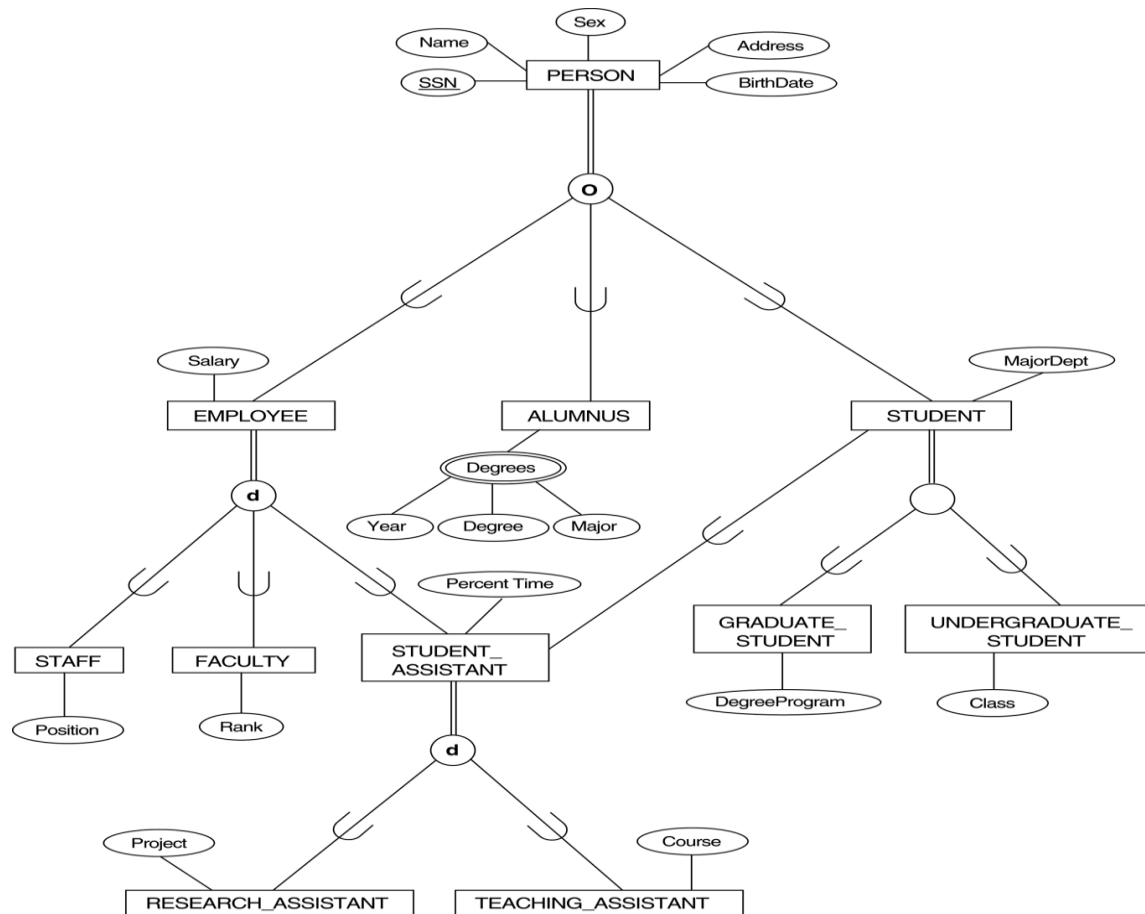

Mapping the EER specialization lattice in using multiple options.

Mapping EER Model Constructs to Relations

Step 9: Mapping of Union Types (Categories).

- ▶ For mapping a category whose defining superclass have different keys, it is customary to specify a new key attribute, called a surrogate key, when creating a relation to correspond to the category.

- ▶ In the example below we can create a relation OWNER to correspond to the OWNER category and include any attributes of the category in this relation. The primary key of the OWNER relation is the surrogate key, which we called OwnerId.

Two categories (union types): OWNER and REGISTERED_VEHICLE.

Mapping the EER categories (union types) in to relations.
